

Assignment3

Kim Bomi and Takuma Andoh

Research Question

Twenty years since the end of Apartheid: Did the collapse of Apartheid play a significant role in reducing racial and social inequality in South Africa? Is post-apartheid South Africa better off or worse off than during the apartheid era?

Definition of Racial and social inequality

Before conducting the data analysis to find the answer for our research question, we begin by clarifying the definitions for racial and social inequality. While social inequality broadly refers to the existence of unequal opportunities for different social status/positions within a society, racial inequality can be seen as one of dimensions of social inequality. It thus indicates the discrimination based on race in access to socioeconomic opportunities or services. In our research study, we will specifically look into racial discrimination in terms of employment, education, and income levels. Because these three indicators within the capitalism society can be seen as fundamental yet significant estimators for the quality of human well-being, we decided to include them. In addition, we will try to identify drivers of unequal income distribution by controlling possible factors and variables such as unemployment rate and education level.

Literature review

In order for us to bring out more in-depth analysis, we undertook background researches by examining the past studies written by various researchers. First of all, according to Leibbrandt,(see Leibbrandt (n.d.)), Since the fall of Apartheid(1993~2008), overall (include all races) income inequality has increased and it was mainly caused by huge inequality within black African community in South-Africa. We chose this article as the first reference since it has been cited the most for the South-African Inequality Study. Second research literature is “One Kind of Freedom: Poverty Dynamics in Post-Apartheid South Africa,”(see Carter and May (2001)) which explores whether the legacy of apartheid in terms of inequality and human insecurity has been superseded by looking at the dynamics of post-apartheid income distribution based on the data from national household surveys. “Income and Non-income Inequality in Post-Apartheid South Africa: What are the Drivers and Possible Policy Interventions?” (see Unit (2009)) identifies the drivers of the reproduction of inequality in post-apartheid South Africa and argues that there had a continuous increase in inequality, strongly indicating that South African is now the one of the most consistently unequal economy in the world. Fourth background research literature is “Poverty and Well-being in Post-Apartheid South Africa: An Overview of Data, Outcomes and Policy.” (see Bhorat and Kanbur (2005)) While this study provides an overview of poverty and well-being of South African during the first decade of post-apartheid, it argues that the first ten years after the end of Apartheid has rather displayed increase in income inequality and unemployment rates. “Crime and local inequality in South Africa” (see Demombynes and ??zler (2005)) examines the effects of local inequality and violent crime in South Africa in the post-apartheid era and claims that racial heterogeneity is highly correlated with all types of crime. Lastly, “Poverty and Inequality Dynamics in South Africa: Post-apartheid Developments in the Light of the Long-Run Legacy” makes a claim that the bottom half of the income distribution and poverty has been dominated by these black South Africans.

Data Gathering based on web-scraping

Closely having studied the past researches, we found that most of researchers made opposite conclusions to ours in regard to the effects of post-apartheid on the quality of life in South Africa. We therefore want to test our hypothesis in the basis of the following data analysis and compare with the past studies.

We found the data of monthly earnings among races and gender. We tried to scrape the data from the website.

```
URL <- 'http://businesstech.co.za/news/wealth/131524/this-is-the-average-salary-in-south-africa-by-race'
```

```
RaceEarningsTable <- URL %>% read_html() %>%  
  html_nodes('#container > div.content_holder > div.content > div.post_single > div.p  
  html_table() %>%  
  as.data.frame  
  
RaceEarningsTable
```

##	X1	X2	X3	X4	X5	X6	X7
## 1		Median	Median	Median	Mean	Mean	Mean
## 2	Race	2003	2012	Increase	2003	2012	Increase
## 3	White	14 468	16 581	15%	11 249	11 991	7%
## 4	Asian/Indian	7 825	11 701	50%	5 264	8 993	60%
## 5	Coloured	4 241	7 058	66%	2 437	3 897	60%
## 6	Black African	4 059	5 445	34%	2 437	2 998	23%

```
URL <- 'http://businesstech.co.za/news/wealth/131524/this-is-the-average-salary-in-south-africa-by-race'
```

```
GenderEarningsTable <- URL %>% read_html() %>%  
  html_nodes('#container > div.content_holder > div.content > div.post_single > div.p  
  html_table() %>%  
  as.data.frame  
  
GenderEarningsTable
```

##	X1	X2	X3	X4	X5	X6	X7
## 1		Median	Median	Median	Mean	Mean	Mean
## 2	Race	2003	2012	Increase	2003	2012	Increase
## 3	Male	5 963	8 299	39%	3 375	4 317	28%
## 4	Female	4 849	6 399	32%	2 435	3 118	28%

Data Cleaning and Merging

In this section, we will try to clean the data so that they can be statistical analysed.

Firstly, we use command “summary” to investigate the structure (class of variables, number of vectors) of data frames we got in the previous section.

```
summary(RaceEarningsTable)
```

```
##      X1      X2      X3  
## Length:6      Length:6      Length:6  
## Class :character Class :character Class :character  
## Mode :character Mode :character Mode :character  
##      X4      X5      X6  
## Length:6      Length:6      Length:6  
## Class :character Class :character Class :character  
## Mode :character Mode :character Mode :character
```

```
##      X7
## Length:6
## Class :character
## Mode  :character
```

```
summary(GenderEarningsTable)
```

```
##      X1      X2      X3
## Length:4    Length:4    Length:4
## Class :character Class :character Class :character
## Mode  :character Mode  :character Mode  :character
##      X4      X5      X6
## Length:4    Length:4    Length:4
## Class :character Class :character Class :character
## Mode  :character Mode  :character Mode  :character
##      X7
## Length:4
## Class :character
## Mode  :character
```

As shown, every variables has a class of “characters” even though it represents numerical data.

The data we want to have is the mean of earnings among races and gender in 2003, 2012.

Firstly, we make TimeVector and IndividualVector to labeling the data.

```
TimeVector <- c(2003,2012) #numerical vector
IndividualVector <- c("Male","Female","White","Asian/Indian","Coloured","BlackAfrican") #character vector
```

Then, we try to convert character vector to numerical vector.

```
male2003 <- as.numeric(gsub("[0-9]+.*$", "\\1", str_replace_all(GenderEarningsTable$X5[3], fixed(" ")
is.numeric(male2003)
```

```
## [1] TRUE
```

```
male2003
```

```
## [1] 3375
```

As I shown above, the character variable successfully converted to numerical variable. Then, we make function which conduct this sequence.

```
Converter <- function(x){
y <- as.numeric(gsub("[0-9]+.*$", "\\1", str_replace_all(x, fixed(" "), "")))
return(y)
}
test <- Converter(x = GenderEarningsTable$X5[3])
is.numeric(test)
```

```
## [1] TRUE
```

```
test
```

```
## [1] 3375
```

Then, we can apply this function to all data.

```
#definition of vector
Earnings2003 <- c(0,0,0,0,0,0)
Earnings2012 <- c(0,0,0,0,0,0)
```

```

#GenderEarnings
for(i in 3:4){
  Earnings2003[i-2] = Converter(x = GenderEarningsTable$X5[i])
  Earnings2012[i-2] = Converter(x = GenderEarningsTable$X6[i])
}
#RaceEarnings
for(i in 3:6){
  Earnings2003[i] = Converter(x = RaceEarningsTable$X5[i])
  Earnings2012[i] = Converter(x = RaceEarningsTable$X6[i])
}
Earnings2003

## [1] 3375 2435 11249 5264 2437 2437
Earnings2012

## [1] 4317 3118 11991 8993 3897 2998
preEarnings <- data.frame(IndivisualVector,Earnings2003, Earnings2012)
preEarnings

```

```

##   IndivisualVector Earnings2003 Earnings2012
## 1             Male          3375          4317
## 2             Female          2435          3118
## 3              White          11249         11991
## 4   Asian/Indian          5264          8993
## 5       Coloured          2437          3897
## 6   BlackAfrican          2437          2998

```

The preEarnings is messy data.

So we are going to transform it into tidy data.

```

library(tidyr)
Earnings <- gather(preEarnings, time, mean, Earnings2003:Earnings2012)
Earnings

```

```

##   IndivisualVector      time  mean
## 1             Male Earnings2003 3375
## 2             Female Earnings2003 2435
## 3              White Earnings2003 11249
## 4   Asian/Indian Earnings2003 5264
## 5       Coloured Earnings2003 2437
## 6   BlackAfrican Earnings2003 2437
## 7             Male Earnings2012 4317
## 8             Female Earnings2012 3118
## 9              White Earnings2012 11991
## 10   Asian/Indian Earnings2012 8993
## 11       Coloured Earnings2012 3897
## 12   BlackAfrican Earnings2012 2998

```

We succeeded to make the numerical vector showing the earnings among races and genders.

Data Gathering by using Data-API

Then, we try to gather data from WorldBank by using Worldbank Data API.

We found the GINI index of south africa.

```
gini <-WDI(country = "ZA", indicator = "SI.POV.GINI")
gini
```

```
##   iso2c      country SI.POV.GINI year
## 1    ZA South Africa      63.38 2011
## 2    ZA South Africa      NA 2010
## 3    ZA South Africa      NA 2009
## 4    ZA South Africa      63.01 2008
## 5    ZA South Africa      NA 2007
## 6    ZA South Africa      64.79 2006
## 7    ZA South Africa      NA 2005
```

We succeeded to fetch the data by using WDI.

Conduct basic descriptive statistics

The data we gathered in previous section partially statistically analysed (mean and median are already calculated). In this section, we try to figure out the trend of inequality graphically by using descriptive statistics.

We want to plot the data frame in earning mean vs time among each individual.

```
jikan <- c(2003,2003,2003,2003,2003,2003,2012,2012,2012,2012,2012,2012)
plot(jikan,Earnings$mean)
```

Then, We try to plot the GINI coefficient of South Africa.

```
qplot(gini$year,gini$SI.POV.GINI)
```

```
## Warning: Removed 4 rows containing missing values (geom_point).
```

Briefly discribing

As shown in the first graph, we cannot say that the inequality is decreased. This results contradicts to our hypothesis.

In the second graph, we can see that the GINI index is slightly increased during 2008~2011. This means that the overall inequality has been increased during this period.

We need further data between 1990~2016 to reject our hypothesis. Because we need both data before and after the fall of Apartheid.
